A Structural End-State Model in Darke Theory

Terminal Closure and the Exhaustion of Admissible Reorganisation

James A. Darke

March 2026

Abstract

This paper develops a technical end-state model for the universe within Darke Theory. Standard cosmological end-state pictures are typically framed in thermodynamic, geometric, or vacuum-instability terms. By contrast, Darke Theory identifies a deeper structural criterion: a universe reaches its true terminal state when admissible structural reorganisation is exhausted under globally dominant closure. This condition is termed *terminal closure*. It is not annihilation, and it is not merely low-gradient thermodynamic equilibration. Rather, it is the asymptotic condition in which residual structure remains extant while the lawful capacity for meaningful future reconfiguration tends to zero. We introduce a minimal formal framework for closure density, admissible state space, and reorganisational capacity; state a theorem chain linking closure accumulation to admissibility compression and asymptotic reorganisational nullity; distinguish terminal closure from heat death, recollapse, vacuum decay, and cyclic renewal; and identify both empirical signatures and potential failure conditions for the model. The resulting picture is that of a structurally frozen universe: not empty, but completed beyond lawful novelty. This establishes terminal closure as the end-state dual of cosmic creation in Darke Theory.

1 Introduction

A theory of origin that cannot also address termination is incomplete. If a framework claims to explain how structure emerges, how lawful distinctions stabilise, and how coherent organisation accumulates from an initially underdetermined regime, then that same framework must also account for the opposite asymptotic limit: the state in which lawful structural becoming is no longer possible.

Darke Theory already supplies the generative side of this picture through recursive differentiation, stabilised refinement, admissibility, and closure. The present paper develops the terminal side. Its central claim is that cosmic finality is not fundamentally defined by low temperature, maximal entropy, geometric recontraction, or catastrophic vacuum transition. Those may describe particular physical scenarios, but none by itself identifies the most fundamental end-state invariant. The deeper question is whether any lawful future of meaningful structure remains.

The answer proposed here is that a universe reaches its true end-state when the space of admissible future reorganisations collapses asymptotically to zero under globally dominant closure. This terminal condition is called *terminal closure*.

The importance of this shift is substantial. It replaces a merely thermodynamic or kinematic account of the end with a structural one. The relevant quantity is not simply whether energy gradients persist, but whether lawful transformation remains available. Residual structures may still exist, and formal temporal parametrisation may still be possible, but if no admissible future of meaningful reorganisation remains, then cosmic history has ended in the only sense that matters structurally.

The paper proceeds as follows. Section 2 explains why familiar end-state descriptions are not sufficient at the level required by Darke Theory. Section 3 recalls the core concepts on

which the argument depends. Section 4 introduces a minimal formal framework for closure density, admissible state spaces, and reorganisational capacity. Section 5 states the central theorem chain. Section 6 isolates the sufficient criterion for cosmic finality. Section 7 derives the consequences for time and constructive becoming. Section 8 develops the structural symmetry between creation and finality. Section 9 embeds the end-state within a full structural lifecycle from origin to finality. Section 11 compares terminal closure to other end-state models in an analytic format. Section 14 lists model-facing signatures, and Section 15 states what would count against the framework. The remaining sections clarify the scope of the model, draw out its interpretive consequences, and identify natural directions for future development.

The load-bearing thesis of the paper may be stated in a single sentence:

> In Darke Theory, the universe ends when admissible structural reorganisation vanishes under terminal closure, leaving structure intact but futureless.

2 Why Standard End-State Language is Insufficient

The dominant modern language for cosmic finality is thermodynamic. In broad form, heat death describes a state in which free-energy gradients have been flattened to the point that no useful work can be performed. This is a physically meaningful and important notion. However, it is not yet the deepest relevant criterion for Darke Theory.

A thermodynamic state description does not, by itself, answer the structural question: does the universe retain any lawful future of meaningful transformation? A system may be thermodynamically poor yet still admit residual structural rearrangement. Conversely, a system may remain physically extant while being structurally complete, in the sense that no admissible reorganisation remains available. The former is not yet terminal in the Darke Theory sense. The latter already is.

This motivates a basic distinction:

- **Thermodynamic depletion** concerns the loss of usable gradients for work.
- **Structural finality** concerns the loss of lawful future reorganisation.

These may overlap in realistic cosmological scenarios, but they are not identical. A fully satisfactory end-state model should identify the more fundamental invariant and then treat thermodynamic descriptions as special or correlated cases.

Darke Theory therefore proposes that the correct terminal invariant is not energy difference alone, nor entropy alone, nor expansion behaviour alone, but the existence or nonexistence of *admissible future structure*. The end of a universe is not merely the slowing of dynamics. It is the exhaustion of lawful becoming.

This yields a stronger criterion than standard heat death. Heat death says that useful work disappears. Terminal closure says that meaningful lawful future disappears. The latter subsumes the former where appropriate, but is not reducible to it.

3 Core Concepts from Darke Theory

Only a small subset of the broader Darke Theory corpus is needed for the present argument. We recall the relevant components here.

3.1 Recursive Differentiation

Darke Theory begins from the lawful emergence of distinction. Structure does not appear as a pre-given completed inventory of objects. Rather, it is generated through recursive differentiation:

the progressive production of distinguishable, refinable, and stabilisable forms from a less-resolved prior regime.

Recursive differentiation is therefore the generative principle of becoming. It opens structured futures.

3.2 Stabilised Refinement

Differentiation alone does not create a world. Distinctions must be refined into repeatable, coherent, and persistent forms. Stabilised refinement narrows the ambiguity of emerging structure and permits durable organisation.

The universe is therefore not merely a field of distinctions, but a history of distinctions that have become stabilised enough to persist.

3.3 Admissibility

Not every logically describable transformation is lawful. A transformation is *admissible* only if it respects the coherence constraints and closure conditions governing the structures involved. Admissibility is the lawfulness filter on future structure.

Without admissibility, there is no principled distinction between meaningful structural futures and arbitrary imagined rearrangements.

3.4 Closure

Closure is the principle by which a structure becomes self-bounded, self-maintaining, and resistant to arbitrary dissolution or reconfiguration. Closure is what allows stable objects, persistent domains, and coherent architectures to exist.

But closure is ambivalent. It is both productive and restrictive. In intermediate regimes, closure enables stable worlds. In asymptotic regimes, accumulated closure compresses the space of admissible future reorganisation.

3.5 The Beginning–End Symmetry

These ideas already imply a structural duality:

> The universe begins because closure is insufficient to pre-fix completed structure. It ends because closure becomes too dominant to permit lawful structural renewal.

Origin is therefore a regime of *under-closure with high generative freedom.* Termination is a regime of *over-closure with vanishing generative freedom.* This symmetry is central to the present paper.

4 Minimal Formal Framework

We now introduce a minimal technical framework sufficient to state the end-state model with greater precision. This is not a complete dynamical cosmology. It is a structural state framework.

The quantities introduced in this section are intentionally coarse-grained structural observables. They are not yet claimed to be unique microscopic operators, nor are they presented as fully calibrated empirical estimators. Their role here is to state the end-state logic in a disciplined technical form.

4.1 Structured State Space

Let $\mathcal{S}$ denote the effective space of structured cosmic states under consideration. An element $s \in \mathcal{S}$ represents a coarse-grained structured configuration of the universe or of a cosmic domain.

For each state s, let

$$\mathcal{A}(s) \subseteq \mathcal{S}$$

denote the set of admissible successor states from s, understood in the Darke Theory sense: those states reachable by lawful transformation while respecting the relevant coherence and closure constraints.

Definition 1 (Admissible State Space)**.** *For a given structured state s, the* admissible state space *from s is the set $\mathcal{A}(s)$ of all structured states lawfully reachable from s.*

This definition abstracts from microscopic detail. The aim is not to enumerate all microstates, but to capture meaningful structured futures.

4.2 Reorganisational Capacity

The key question is whether $\mathcal{A}(s)$ remains nontrivial in the relevant structural sense.

Definition 2 (Reorganisational Capacity)**.** *For a structured state s, the* reorganisational capacity *$R(s)$ is a coarse-grained effective measure of the lawful, nontrivial, structurally meaningful future reorganisations available from s.*

No specific measure-theoretic form is assumed here. At minimum, $R(s) = 0$ is interpreted as the absence of any meaningful admissible future reorganisation.

At the universe level, if $s(t)$ denotes the effective cosmic state at time t, then

$$R(t) := R(s(t))$$

is the effective global reorganisational capacity.

4.3 Closure Density

We also require a quantity encoding the degree to which existing structure constrains its own future.

Definition 3 (Closure Density)**.** *For a structured state s, the* closure density *$C(s)$ is a coarse-grained effective measure of the extent to which the existing organisation of s restricts its admissible future state space.*

At the universe level,

$$C(t) := C(s(t))$$

denotes the effective global closure density.

In a richer formalism, C might be vector-valued, scale-dependent, or decomposed into multiple closure modes. For the purposes of this paper, it is sufficient to treat it as an effective scalar structural quantity.

4.4 Structural Novelty

The end-state model requires a distinction between mere fluctuation and meaningful future.

Definition 4 (Structural Novelty)**.** *A successor state $s' \in \mathcal{A}(s)$ exhibits* structural novelty *relative to s if the transformation $s \to s'$ produces a nontrivial redistribution, reorganisation, or emergence of coherent structure beyond notational relabelling or dynamically irrelevant fluctuation.*

This keeps $R(s)$ from being artificially inflated by trivial activity.

4.5 Terminal Regime

We can now state the terminal asymptotic relations.

Definition 5 (Global Closure Dominance)**.** *A universe is in a regime of* global closure dominance *if, across sufficiently many scales and domains, closure constraints suppress the emergence of new admissible structurally novel futures.*

Definition 6 (Terminal Closure)**.** *A universe is in* terminal closure *if*

$$\lim_{t\to\infty} R(t) = 0$$

under global closure dominance, while residual structure remains extant.

Residual structure is explicitly permitted. Terminal closure is not equivalent to emptiness.

4.6 Minimal Asymptotic Behaviour

The structural end-state proposed in this paper is captured by

$$\lim_{t\to\infty} C(t) = C_{\max}, \qquad \lim_{t\to\infty} R(t) = 0,$$

where $C_{\max}$ denotes an effective maximal closure regime for the universe under consideration.

At a purely schematic level, the late epoch satisfies

$$\frac{\mathrm{d}R}{\mathrm{d}t} < 0 \quad \text{for sufficiently late } t,$$

and

$$\frac{\mathrm{d}C}{\mathrm{d}t} \geq 0 \quad \text{in the same regime,}$$

or at minimum $C(t)$ is asymptotically nondecreasing.

These expressions should not be read as a fully calibrated empirical system. They are the minimal formal statement of the structural tendency.

5 Theorem Chain for Terminal Closure

The logic of the model is best expressed as a theorem chain rather than a single isolated statement.

5.1 From Closure Accumulation to Admissibility Compression

Proposition 7 (Closure Accumulation Compresses the Admissible Future)**.** *Let s be a structured state. If the closure density $C(s)$ increases without a compensating mechanism that opens new lawful structural freedoms, then the effective admissible state space $\mathcal{A}(s)$ contracts in its structurally meaningful extent.*

Conceptual proof. Closure restricts arbitrary rearrangement by making existing structure self-bounded and self-constraining. Each increase in closure removes at least some candidate successor configurations from admissibility unless a new generative mechanism introduces lawful replacement freedoms. Therefore, in the absence of such compensation, the space of structurally meaningful admissible futures contracts. □

Corollary 8 (Admissibility Compression)**.** *Sustained closure accumulation induces asymptotic admissibility compression.*

Proof. Immediate from the preceding proposition under repeated application over late-time evolution. □

5.2 From Admissibility Compression to Declining Reorganisational Capacity

Proposition 9 (Admissibility Compression Reduces Reorganisational Capacity)**.** *If the structurally meaningful extent of $\mathcal{A}(s)$ contracts asymptotically, then the reorganisational capacity $R(s)$ decreases asymptotically.*

Conceptual proof. Reorganisational capacity is defined as the effective measure of lawful structurally meaningful futures. Compression of the admissible future set in that same structurally meaningful sense necessarily reduces that effective measure. Hence $R(s)$ declines. □

Corollary 10 (Late-Epoch Novelty Suppression)**.** *If admissibility compression persists into the asymptotic regime, then the emergence rate of genuinely novel cosmic structure declines correspondingly.*

5.3 From Vanishing Reorganisational Capacity to Reorganisational Nullity

Definition 11 (Reorganisational Nullity)**.** *A structured system is in* reorganisational nullity *when its reorganisational capacity is null in the relevant asymptotic or effective sense.*

Proposition 12 (Vanishing Reorganisational Capacity Implies Reorganisational Nullity)**.** *If $R(s) = 0$, then the state s is in reorganisational nullity.*

Proof. This is immediate from the definition. If no lawful structurally meaningful future reorganisation remains, then structural becoming has terminated for that system. □

5.4 The Main End-State Theorem

Theorem 13 (Terminal Closure Principle)**.** *Suppose a universe evolves through recursive differentiation, stabilised refinement, admissibility-limited emergence, and progressive closure formation. If, in the asymptotic regime, closure accumulation suppresses the generation of new admissible structural freedoms faster than such freedoms can be replenished, then the universe approaches terminal closure:*

$$\lim_{t\to\infty} R(t) = 0$$

under global closure dominance, while residual structure may remain.

Conceptual proof. Recursive differentiation opens structured futures. Stabilised refinement and closure preserve structure, but every stable closure event also constrains some future rearrangements. If the cumulative effect of closure increasingly dominates the creation of new admissible structural freedoms, then the meaningful admissible state space compresses. By the previous propositions, this reduces reorganisational capacity. If the compression persists asymptotically without compensating generative reopening, then reorganisational capacity tends to zero. The universe therefore reaches terminal closure, with structural persistence but no admissible future of meaningful reorganisation. □

Corollary 14 (Strong Formulation of Cosmic Finality)**.** *In Darke Theory, cosmic death is the exhaustion of admissible structural reorganisation under terminal closure, not merely the disappearance of matter, the loss of temperature gradients, or the cessation of all local motion.*

6 The Finality Criterion

The previous section establishes a derivation chain. We now isolate the decisive criterion.

Proposition 15 (Sufficient Criterion for Cosmic Finality)**.** *If the effective global reorganisational capacity of a universe vanishes in the asymptotic structural sense, then that universe has reached its true end-state.*

Conceptual proof. If effective global reorganisational capacity has vanished, then no lawfully admissible and structurally meaningful future remains possible. Whatever residual structures persist, the universe no longer has a constructive structural future. Hence it has reached its true end-state. □

Remark 16. *The converse may hold under the definitions adopted in this paper, but the present formulation is intentionally stated in one direction only in order to preserve a narrower technical claim.*

This proposition identifies the invariant that the paper claims is fundamental. It is more general than thermodynamic criteria because it speaks directly to the existence of lawful future structure.

7 Time and the Loss of Constructive Becoming

Darke Theory does not treat time as meaningful in total isolation from structure. Parameter time may be formally representable, but the ontological significance of time depends on ordered becoming: lawful transition, consequence, reorganisation, and emergence.

Proposition 17 (Loss of Constructive Temporal Content)**.** *As a universe approaches terminal closure, time need not cease formally, but it loses constructive ontological content because lawful becoming is asymptotically extinguished.*

Conceptual proof. If the significance of time is tied to the ordered realisation of admissible future structure, then the removal of admissible future removes the constructive role of temporal succession. Parameter values may still be assigned, and residual low-level dynamics may still be representable, but these no longer constitute an open history of becoming. Thus time may remain formal while losing its constructive ontological role. □

Corollary 18 (Separation of Persistence from History)**.** *A universe may continue to persist formally after it has ceased to possess meaningful history.*

This point matters. Terminal closure does not require literal temporal annihilation. It requires the end of genuine structural futurehood.

8 Structural Symmetry Between Creation and Finality

The terminal closure model completes a major symmetry in Darke Theory.

At the beginning of cosmic history, closure is insufficient to pre-fix completed structure. The universe is therefore generatively open. Recursive differentiation and stabilised refinement can proceed.

At the end of cosmic history, closure becomes excessively dominant relative to the generation of new admissible freedoms. The universe is no longer generatively open. Structure persists, but lawful novelty is suppressed.

This symmetry may be written schematically as

$$\text{Origin} = \text{under-closure with high generative freedom},$$

$$\text{Termination} = \text{over-closure with vanishing generative freedom}.$$

Remark 19. *The beginning and end of a universe are not opposed as existence and nonexistence. They are opposed as openness to lawful formation and closure against lawful renewal.*

This is not a rhetorical flourish. It is a direct consequence of using closure as a principle that is both enabling and limiting.

9 Lifecycle Model from Origin to Terminal Closure

The end-state can be situated within a complete structural lifecycle. This is not intended as a detailed astrophysical chronology. It is a structural sequence.

1. **Pre-structural openness.** Closure is insufficient to lock completed structure in advance.
2. **Recursive differentiation.** Lawful distinctions emerge from a less-resolved prior regime.
3. **Stabilised refinement.** Distinctions sharpen into coherent and persistent forms.
4. **Local closure formation.** Stable domains, objects, and relation-patterns become self-bounded and self-maintaining.
5. **Coherence architecture growth.** Larger-scale structural order accumulates across the universe.
6. **Closure accumulation.** The very success of stable organisation increasingly constrains future admissibility.
7. **Admissibility compression.** The meaningful lawful future narrows across domains and scales.
8. **Reorganisational exhaustion.** Novel admissible reorganisations become sparse and asymptotically negligible.
9. **Terminal closure.** Residual structure remains, but the universe is futureless in the structural sense.

The endpoint is therefore not alien to the origin story. It is its terminus.

10 Residual Structure and Structural Freezing

A frequent misconception about cosmic end-states is that finality requires emptiness. Darke Theory does not require that. A terminally closed universe may still contain residual structures, such as long-lived coherence basins, relic domains, persistent shells, or other highly stable configurations.

What matters is not whether something remains, but whether what remains can still lawfully become something structurally new.

This leads to a precise distinction:

- **Existence** concerns whether residual structures persist.
- **Futurehood** concerns whether lawful structural becoming remains open.

Terminal closure preserves the former while extinguishing the latter.

The phrase *structurally frozen universe* is therefore appropriate, provided it is understood correctly. The claim is not that the universe becomes literally solid in a material sense. The claim is that the universe becomes reorganisationally rigid. It persists as completed structure without a meaningful admissible future.

11 Comparison with Other End-State Models

This section compares terminal closure with familiar end-state pictures using explicit criteria.

11.1 Comparison Criteria

For each model, we ask:

a. What is the criterion of death?

b. Is residual structure permitted?

c. Is the model fundamentally thermodynamic, geometric, or structural?

d. Does the model require catastrophic transition?

e. Can lawful structural novelty remain?

11.2 Heat Death

Criterion of death. Asymptotic loss of usable free-energy gradients and thermodynamic flattening.

Residual structure. Residual structure is permitted.

Primary character. The model is fundamentally thermodynamic.

Catastrophic transition required. No catastrophic transition is required.

Lawful structural novelty. Whether lawful structural novelty remains is not specified by thermodynamics alone and therefore remains structurally ambiguous without further assumptions.

Contrast with terminal closure. Heat death does not by itself determine whether meaningful admissible structural futures remain. Terminal closure does. For that reason, terminal closure is structurally deeper than heat death, even in cases where the two may overlap empirically.

11.3 Big Crunch

Criterion of death. Global recollapse into a dense terminal state.

Residual structure. Residual structure is typically not preserved in any ordinary sense, though detailed models vary.

Primary character. The model is fundamentally geometric and dynamical.

Catastrophic transition required. A strong global transition is generally required, usually in the form of recontraction.

Lawful structural novelty. Whether lawful structural novelty remains is model-dependent.

Contrast with terminal closure. Terminal closure does not require recontraction. It is compatible with continued expansion, asymptotic dilution, or other large-scale kinematic behaviours, provided reorganisational capacity tends to zero.

11.4 Vacuum Decay

Criterion of death. Transition to a lower vacuum state through nucleation or an analogous instability process.

Residual structure. Residual structure is typically destroyed or radically altered.

Primary character. The model is fundamentally one of field-theoretic instability.

Catastrophic transition required. Yes. A catastrophic transition is intrinsic to the model.

Lawful structural novelty. For the original universe, lawful structural novelty typically becomes irrelevant once the transition begins.

Contrast with terminal closure. Vacuum decay describes catastrophic replacement. Terminal closure describes asymptotic exhaustion. The former is a destructive event; the latter is the completion of structural constraint.

11.5 Cyclic Renewal

Criterion of death. A strict terminal condition is often absent, since one cosmic phase transitions into another.

Residual structure. Whether residual structure is preserved depends on the particular cyclic model.

Primary character. The model is framework-dependent and may combine thermodynamic, geometric, or structural elements.

Catastrophic transition required. Some form of bounce, reset, or renewal condition is usually required.

Lawful structural novelty. Yes, provided renewal occurs.

Contrast with terminal closure. The present paper develops the strict non-cyclic case. It does not deny that a future Darke Theory extension might explore whether over-closure becomes inadmissible and forces a new differentiating phase. It simply does not assume that here.

11.6 Why Terminal Closure is More Fundamental

Each alternative model identifies some physically important feature: energy depletion, recontraction, instability, or recurrence. Terminal closure instead asks the deepest structural question: does any lawful future of meaningful reorganisation remain?

That question is more fundamental because it can classify physically distinct scenarios under one invariant. A universe may cool, expand, collapse, or remain populated by relic structures; the decisive issue is whether it still possesses admissible futurehood. If not, then it is terminal regardless of its specific physical presentation.

12 Local and Global Reorganisational Nullity

The end-state principle is not confined to whole-universe analysis. It also applies hierarchically.

Definition 20 (Local Reorganisational Nullity)**.** *A subsystem is in* local reorganisational nullity *when its reorganisational capacity is effectively null under its prevailing closure regime.*

Definition 21 (Global Reorganisational Nullity)**.** *A universe is in* global reorganisational nullity *when the effective reorganisational capacity of the universe as a whole is asymptotically null under global closure dominance.*

This hierarchy matters because it shows that terminal closure is not an isolated cosmological curiosity. It is the large-scale extension of a general structural law. Systems, organisms, stars, civilisations, galaxies, and cosmic domains may all undergo local reorganisational nullity prior to global reorganisational nullity.

The global end-state is therefore the universalisation of a principle already visible in finite structural systems: what persists without admissible future is structurally finished.

13 Model Status and Scope

The present paper is a structural framework whitepaper, not yet a fully parameterised cosmological dynamics paper. That distinction should be explicit.

The model presently supplies:

- a precise end-state concept,
- a minimal formal language for admissibility, closure, and reorganisational capacity,
- a theorem chain linking closure accumulation to cosmic finality,
- a structural comparison with existing end-state pictures,
- and a set of possible late-epoch signatures and failure conditions.

The model does *not* yet supply:

- a unique numerical operator for $C(t)$,
- a calibrated observational estimator for $R(t)$,
- a complete cosmological field equation for closure dynamics,
- or a direct fit to observational late-universe data.

This is intentional. The present goal is to identify the correct structural invariant and establish the end-state logic cleanly before overcommitting to a specific empirical parametrisation.

14 Potential Empirical Signatures

A structural end-state model should generate at least provisional expectations about the late-universe regime. The following signatures are therefore not presented as already-confirmed results, but as model-facing consequences.

14.1 Declining Rate of Genuine Structural Novelty

If terminal closure is the correct asymptotic picture, then the rate at which genuinely new coherent structural regimes emerge should decline monotonically in late epochs, or at least trend downward strongly over sufficiently large scales.

14.2 Persistence Dominance

Existing coherence basins should increasingly dominate over newly emergent large-scale structures. Late cosmic history should be characterised less by fresh structural richness and more by the continued persistence of already-established forms.

14.3 Admissibility Compression Across Scales

The space of macroscopically meaningful lawful cosmic reorganisations should narrow. Even if local activity remains, the number of genuinely distinct large-scale futures should diminish.

14.4 Increasing Separation Between Residual Motion and Creative Motion

A terminally approaching universe should exhibit a widening gap between low-level dynamics still occurring and dynamics still capable of producing meaningful structural novelty.

14.5 Asymptotic Rigidity of Large-Scale Structural Architecture

Large-scale cosmic organisation should become progressively more resistant to redirection into new coherent regimes. This is the practical observational face of increasing closure dominance.

These are deliberately broad because the present paper is foundational. A later empirical paper could attempt to define late-time proxies for $C(t)$ and $R(t)$ more explicitly.

15 Failure Conditions and Falsifiability Guidance

A structural end-state model should state what would count against it. The following would weaken or falsify the present framework.

15.1 Persistent Late-Epoch Generation of Novel Coherent Structure

If the universe were shown, in the relevant asymptotic regime, to continue generating genuinely new large-scale coherent structural modes without corresponding loss of admissibility, then the claim that closure accumulation dominates would be undermined.

15.2 Demonstrable Nonvanishing Reorganisational Capacity at Asymptotic Scales

If a defensible cosmic estimator of meaningful reorganisational capacity were constructed and shown not to tend toward zero in the late regime, then terminal closure in its present form would be false or incomplete.

15.3 A Closure Measure Decoupled from Future Compression

If increased closure were shown not to compress the admissible future, then the theorem chain of this paper would fail at its first load-bearing link.

15.4 A Valid Global Reopening Mechanism

If Darke Theory or observation demanded a lawful mechanism by which asymptotic over-closure necessarily reopens admissible structural futures, then the strict non-cyclic terminal model presented here would have to be replaced or subordinated to a cyclic or rebound variant.

15.5 Thermodynamic Terminality with Persistent Structural Futurehood

If a universe could be shown to satisfy heat-death-like conditions while still retaining a rich admissible structural future, then thermodynamic depletion and structural finality would be empirically separated even more sharply. This would not necessarily refute terminal closure, but it would require more careful articulation of the relation between thermodynamic and structural end-state concepts.

These failure conditions matter because they discipline the framework. The present model is not intended as an untouchable metaphysical declaration. It is a structural proposal that should survive contact with stronger formalisation and eventual empirical pressure.

16 Interpretive Consequences

Several broad consequences follow from the model.

16.1 The Final Universe is Completed, Not Erased

Terminal closure describes completion beyond lawful novelty, not nullity. The end-state is therefore stronger than disappearance and more intelligible than a mere statement of thermodynamic flattening.

16.2 Closure Makes and Ends Worlds

Closure is not an external destroyer of structure. It is the same principle that makes stable worlds possible. Its terminal role is therefore internal to the logic of creation itself.

16.3 Time Depends on Futurehood for its Constructive Meaning

Where admissible futurehood vanishes, time loses its role as the medium of becoming. Formal succession may remain, but history does not.

16.4 Creation and Finality are Two Poles of One Law

Darke Theory gains a major completion through this paper. Origin and end are no longer disconnected mysteries. They become opposite regimes of one structural principle:

> creation through insufficient closure for completion, and termination through excessive closure for renewal.

17 Future Extensions

Several natural extensions follow.

1. Construction of a richer mathematical operator for closure density C.
2. Construction of a coarse-grained estimator for reorganisational capacity R.

3. Investigation of relations between R, entropy-like measures, and large-scale coherence metrics.
4. Domain-specific modelling of local reorganisational nullity in astrophysical systems.
5. A companion paper testing whether total closure may itself become structurally inadmissible, thereby opening a cyclic Darke Theory variant.

The present paper intentionally remains on the strict non-cyclic side. Its job is to establish the terminal case cleanly first.

18 Conclusion

This paper has developed a structural end-state model for the universe within Darke Theory. The central claim is that the true terminal condition of a universe is not defined solely by temperature flattening, vanishing usable gradients, recollapse, or catastrophic vacuum transition. It is defined by the exhaustion of admissible structural reorganisation under globally dominant closure.

This end-state, termed *terminal closure*, is the asymptotic regime in which effective closure density approaches maximal dominance while reorganisational capacity tends to zero. Residual structure may remain, but it remains only as completed, futureless structure. The universe is not annihilated. It is structurally finished.

The model strengthens the concept of cosmic finality in two ways. First, it identifies a deeper invariant than thermodynamic death alone: the presence or absence of lawful futurehood. Second, it completes a major symmetry within Darke Theory itself. If creation is the opening of lawful structural possibility, then the end of the universe is the closure of lawful structural possibility.

The final universe is therefore not best described as merely cold, empty, or dilute. It is a universe in which no meaningful admissible future remains. It persists, but it no longer becomes.

Compressed Thesis Statement

> In Darke Theory, the universe ends when admissible structural reorganisation vanishes under terminal closure, leaving residual structure intact but futureless.

Axiom Dependency Summary

This paper depends conceptually on the following Darke Theory commitments:

- **Recursive differentiation**: structure emerges through lawful distinction rather than being fully presupposed.
- **Stabilised refinement**: persistence requires refinement into coherent organisation.
- **Admissibility**: not every conceivable transformation is lawful.
- **Closure**: stable structure exists by becoming self-constraining and self-bounded.
- **Closure consequence**: accumulated closure compresses admissible future freedom.
- **Structural time**: time gains ontological significance through lawful becoming.

The terminal closure model is therefore not an auxiliary appendage. It is the natural end-state consequence of the same principles used elsewhere in the Darke Theory corpus to explain emergence, persistence, and structured reality.
